Thermally Rearranged Polymer Membranes Containing Tröger’s Base Units Have Exceptional Performance for Air Separations

Stephen M. Meckler, Jonathan E. Bachman, Benjamin P. Robertson, Chenhui Zhu, Jeffrey R. Long, and Brett A. Helms*

Abstract: The influence of segmental chain motion on the gas separation performance of thermally rearranged (TR) polymer membranes is established for TR polybenzoxazoles featuring Tröger’s base (TB) monomer subunits as exceptionally rigid sites of contortion along the polymer backbone. These polymers are accessed from solution-processable ortho-acetate functionalized polyimides, which are readily synthesized as high-molecular-weight polymers for membrane casting. We find that thermal rearrangement leads to a small increase in d-spacing between polymer chains and a dramatic pore-network reconfiguration that increases both membrane permeability and O₂/N₂ selectivity, putting its performance above the 2015 upper bound.

Mass transport across polymer membranes is mediated by segmental chain motion of the polymer backbone. Consequently, increased backbone rigidity improves diffusive selectivity, albeit at the expense of permeability. To enhance permeability as well as selectivity, measures to increase inter-chain spacing are often required. Within this framework of polymer design, permeability-selectivity tradeoffs manifest as upper bounds to membrane performance, as articulated by Robeson.[2,3] Upper-bound polymers for membranes, such as polymers of intrinsic microporosity (PIMs) and TR polymers, are thus highly contorted, inefficiently packed, and glassy.[4] To advance beyond these limits, new polymer backbones are needed that incorporate more rigid contortion sites that introduce free-volume elements in the membrane and slow segmental chain motion for higher diffusive selectivity, while also incorporating a means to increase inter-chain spacing, for example, via controlled solid-state chemical rearrangements, to further enhance membrane permeability.

Herein we show that rationally designed, conformationally rigid monomers, when incorporated into TR polybenzoxazole membranes, yield highly permeable, size-selective micropore networks with exceptional discrimination between gases with small diffusion correlation diameters, including dioxygen and dinitrogen. Key to the success of this approach is the implementation of TB as the site of contortion along the TR polymer backbone (Figure 1). Perturbations to the dihedral angle of TB incur substantially higher energetic penalties than spiro-centers used in conventional TR polymers;[5] as a result, solid-state decarboxylation of ortho-

functional polyimides containing these inflexible moieties yields rigid-rod polybenzoxazole membranes with small pores that enhance permeability and, for multiple important gas pairs, selectivity. This new class of TR polymers is accessed through ortho-acetate functionalized Tröger’s base polyimide precursors: for example, 6FDA-AcTB 1, ODPA-AcTB 2, and BPADA-AcTB 3 (Scheme 1). Notably, thermal rearrangement of 6FDA-AcTB 1 to 6FDA-TR-TB 4 (Figure 1) produces membranes with a unique pore architecture that endows them with an O₂ permeability of 108 Barrer and O₂/N₂ selectivity of 8.9, placing the performance above the 2015 air-separation upper bound and highlighting new opportunities in membrane design with this strategy.⁷

Our approach provides distinct advantages over state-of-the-art membrane materials for air separations. Traditional glassy polyimides (PIs) fall below the Robeson upper bound, and systems incorporating these membranes are permeability-limited for their range of selectivities.⁶ Solution-processable microporous polymers, including PIMs and PIM-PIs, provide permeability gains over polyimides, albeit with little to no gains in selectivity; as such, their use in air separations comes with added system complexity and cost associated with low product recovery. Selectivity gains over PIMs with TR polymers are thus attractive for air separations, but commensurate permeability gains are needed to fully realize the separation potential of TR polymer membranes.⁶ In particular, what is lacking is a dedicated means of rigidifying the membrane while also increasing inter-chain spacing, a method uniquely implemented herein.

To access conformationally rigid TR polymer membranes, we synthesized ortho-acetate precursor polyimides (AcTBs) that incorporate bicyclic TB units such that the thermal rearrangement yields a benzoazole on each aromatic ring of the foundational architectural motif. AcTBs were synthesized through the condensation polymerization of ortho-hydroxy Tröger’s base diamine 6 with a desired diacylhydride (Scheme 1).

The diamine monomer was synthesized through the reaction of 4-amino-2-nitrophenol 5 with paraformaldehyde followed by hydrogenation of the nitro groups. Single-crystal X-ray diffraction revealed that the amine substituents are regiospecifically ortho to the Tröger’s base bridge, flanked on both sides by methylene and hydroxyl groups. Steric hindrance at the amine potentially limits access to high molecular weight polymers, but we overcame this limitation by silylating the amine prior to polymerization using chlorotrimethylsilane (TMS-Cl), 4-(dimethylamino)pyridine (DMAP) as an silylation catalyst, and pyridine as an acid scavenger.⁹ Importantly, silylation increases electron density on the amine, activating the monomer for polymerization.¹² After silylation, the diacylhydride monomer was introduced into the reaction mixture to begin polymerization. Dehydration of the resulting polymer with an excess of acetic anhydride yielded the polyimide, whose ortho-hydroxy groups were concomitantly acetylated. The resulting AcTB polymers possessed high molecular weights (Figure S1 in the Supporting Information) and excellent solubility for membrane casting.

To assess the scope of this polymerization scheme and understand architectural outcomes, AcTB polymers 1–3 were synthesized from three different diacylhydride monomers: 4,4’-(hexafluorosopropylidene)diphthalic anhydride (6FDA), 4,4’-oxydiphthalic anhydride (ODPA), and 4,4’-(4,4’-isopropylidenediphenoxy)bis(phthalic anhydride) (BPADA). No glass transition was observed up to 325°C for 6FDA-AcTB 1 or ODPA-AcTB 2, but a clear transition was recorded at Tₘ = 294°C for BPADA-AcTB 3 (Figure S2). The BET surface area, as measured by nitrogen gas adsorption at 77 K, dropped precipitously with the removal of bulky trifluoromethyl substituents (172 m²⋅g⁻¹ for 6FDA-AcTB 1 vs. 51 m²⋅g⁻¹ for ODPA-AcTB 2, Figure S3), and when excess flexibility was introduced in BPADA-AcTB 3, no N₂ uptake was observed. These results demonstrate that the physical properties and pore networks of AcTB polymers (and films) are tunable through chemical design of the diacylhydride. Further, the highly glassy and porous nature of 6FDA-AcTB...
suggests it would be the most promising membrane material for air separations; as such, it was further investigated through the full TR reaction pathway.

TR-TB polymer membranes accessed through the solid-state decarboxylation of AcTB polyimide films feature the rigidity of the polybenzoxazole structure, enhanced porosity from polymer chain reconfiguration, and complementary intra-chain rigidity and frustrated inter-chain packing from the TB sub-unit. To understand the thermal reaction pathway through which 6FDA-AcTB proceeds, we employed thermo-gravimetric analysis coupled with mass-spectrometry (TGA-MS). During thermal rearrangement, two mass loss events are expected: the first loss results from elimination of acetate groups, producing ketene and leaving behind a hydroxy group; carbon dioxide is then driven off during rearrangement to the benzoxazole. Figure 2a shows total mass loss and relative intensities of the ketene and carbon dioxide mass peaks as a function of temperature. Acetate loss begins around 300°C and peaks just below 400°C. As the thermal rearrangement reactions can be sequential, 400°C considered the lower-bound temperature for thermal rearrangement in this system. Carbon dioxide evolution is marked by a local maximum around 450°C, coinciding with a peak in the first derivative mass loss (Figure S4a), consistent with the proposed polybenzoxazole formation mechanism.

To maximize conversion to the benzoxazole while minimizing polymer backbone decomposition, care must be taken in developing thermal rearrangement protocols, which typically involve a high-temperature isothermal soak. Ideally, the experimental mass loss is equivalent to the theoretical value. Isothermal TGA experiments were used to monitor TR conversion at different soak temperatures. Films were heated at 5°C min⁻¹ to 300°C under flowing argon and held at that temperature for 1 h to fully imidize the polymer and drive off any residual solvent. The films were then heated at 5°C min⁻¹ to a final soak temperature varying between 400–440°C. The theoretical 22.2% mass loss for complete thermal rearrangement was reached in approximately 7 min at 440°C, 27 min at 420°C, and 94 min at 400°C (Figure S4b). Based on these findings, we adopted a final soak temperature of 420°C for 30 min. Large-format membranes were thermally treated in a tube furnace under flowing argon. Thermally-treated films were insoluble in all solvents tested, as is common for TR polymers.

To understand the influence of thermal treatment on analyte transport through AcTB polymer films, we measured the permeability of CO₂, O₂, N₂, and CH₄ through films of 6FDA-AcTB and 6FDA-TR-TB. For all four gases, permeability increases with thermal rearrangement, from 17 to 108 Barrer for O₂, 72 to 158 Barrer for CO₂, 3.9 to 12 Barrer for N₂, and 3.4 to 6.7 Barrer for CH₄. Smaller gases generally exhibit the greatest enhancements (Figure 3a). The less pronounced increase in CO₂ permeability, which is largely dictated by solubility, suggests that the observed enhancements are diffusivity-driven. The increase in O₂ permeability is most significant, improving both permeability and selectivity for O₂/N₂ separations and placing the membrane far above the upper bound proposed in 2008 and slightly above the more recently suggested 2015 upper bound (Figure 3b). The chemical origins of these membrane performance enhancements were investigated spectroscopically. Carbon X-ray photoelectron spectroscopy (XPS) revealed that both 6FDA-AcTB and 6FDA-TR-TB have a broad peak near 284 eV, as well as a small peak at 293 eV from trifluoromethyl carbons (Figure S5a). Of note, the carbonyl carbon peak near 288 eV in the 6FDA-AcTB spectrum is greatly diminished in the 6FDA-TR-TB spectrum. This result suggests success-

Figure 2. Characterization of the thermal rearrangement reaction and the related structural evolution. a) TGA-MS of 6FDA-AcTB heated to 600°C at a ramp rate of 10°C min⁻¹. b) CO₂ adsorption isotherms at 273 K and c) WAXS patterns of 6FDA-AcTB and 6FDA-TR-TB.
While restricted intra-chain mobility arising from local chemical changes can account for some membrane performance attributes, global pore-network evolution during thermal rearrangement is also important in dictating transport outcomes. Carbon dioxide adsorption isotherms collected at 273 K show higher uptake in 6FDA-TR-TB 4 vs. 6FDA-AcTB 1, consistent with the predicted porosity increase and the observed permeability increase with thermal rearrangement (Figure 2b). Nonlocal DFT pore-size distributions produced from these isotherms reveal significant ultramicroporosity (i.e., pores of diameter < 7 Å, Figure S6). The isotherms and pore-size distributions were similar for both polymers, motivating further study of the pore networks with synchrotron wide-angle X-ray scattering (WAXS, Figure 2c). A small decrease in the peak position of the main scattering feature near 1 Å⁻¹ reflects an increase in average inter-chain d-spacing from 6.3 Å in 6FDA-AcTB 1 to 6.5 Å in 6FDA-TR-TB 4. This increased inter-chain spacing is consistent with increased porosity and permeability. Notably, a shoulder feature in the 6FDA-AcTB 1 scattering pattern corresponding to 4.7 Å disappears from the 6FDA-TR-TB 4 scattering pattern, and the feature corresponding to 3.5 Å grows in relative intensity and broadness after thermal rearrangement.

These changes to the WAXS patterns with thermal rearrangement could signal the coalescence of pores into more uniform free-volume elements with spacing between the diameters of O₂ and N₂. Polymer segments too inflexible to exhibit segmental chain motion-dictated transport may be exhibiting a molecular sieving effect; such a shift in transport mechanism would explain the marked increase in O₂/N₂ selectivity despite more modest performance increases in CO₂/CH₄ and CO₂/N₂ separations (Figure S7). High-q scattering features in porous polymer WAXS patterns, however, sometimes reflect distances between given repeat units rather than the space between chains.⁹ Even if the scattering peaks arise from the positions of the repeat units, the results still signal a shift to a more uniform distribution of occupied volume in the porous material. Overall, characterization of the TR polymer pore network suggests that an increase in pore size and total porosity is responsible for the enhanced permeability while the formation of immobile size-discriminating windows enhances size-selectivity for air separations.

The exceptional performance of 6FDA-TR-TB 4 membranes and the characterization of their pore network validate our design strategy of incorporating conformationally rigid units, such as TB, into a TR polybenzoxazole to produce highly selective membranes without sacrificing permeability. We propose that these membranes could be relevant in applications where inert gas production is needed in confined areas, such as backfilling fuel tanks on aircraft. We note that the permselectivity of TR-TB membranes could be further tuned through the chemical structure of the diamhydride residue, but the rational design of more conformationally rigid motifs is necessary to substantially advance TR polymer membranes. Strategies to this end will likely include the development of sterically hindered polycyclic monomers, an approach that has seen recent success in advanced PIMs.¹⁰ Leading-edge materials genomics screens may be an effective
